

2 Optical attenuation of the beam splitter

Overview

Signal attenuation refers to the reduction in the intensity of a light beam as it passes through a medium or a device. In the context of beam splitters, attenuation can occur due to several factors, including absorption, reflection, and scattering. Electric elds E_1 and E_2 enter input ports 1 and 2. A beam splitter or beamsplitter is an optical device that splits a beam of light into a transmitted and a reflected beam. It is a crucial part of many optical experimental and measurement systems, such as interferometers, also finding widespread application in fibre optic telecommunications. Output states from beam splitters under different inputs such as single photons entering through one port, two photons entering through the two. on non-absorbing beam splitters.

In its most common form, a cube, a beam splitter is made from two triangular glass prisms which are glued together at their base using polyester, epoxy, or urethane-based adhesives. (Before these synthetic resins, natural ones were used, e.g. Canada balsam.) The thickness of the resin layer is adjusted such that (for a certain wavelength) half of the light incident through one "port" (i.e., face of the cube) is reflected and th
