

How to determine the order of optical splitters in telecommunications systems

Overview

Its basic form is "OLT → Optical Splitter → ONU", and the splitting ratio of the optical splitter used here is usually 1:64. By dividing a single optical signal from a central Optical Line Terminal (OLT) into multiple outputs for Optical Network Terminals (ONTs) at users' homes, splitters eliminate the need for dedicated fibers to each residence—slashing infrastructure costs while scaling network reach. 1x32 splits were common in North America for G-PON architectures. As XGS-PON continues to be adopted, some service. Optical splitters, encompassing FBT (Fused Biconical Taper) couplers and PLC (Planar Lightwave Circuit) splitters, are prevalent passive optical devices designed to divide fiber optic light into multiple segments based on a specified ratio. A key challenge is determining how many users a single OLT port can support, which is defined by the split ratio. Traditional GPON networks often employ 1:32 or 1:64 splits. To deploy a successful FTTH network, one must consider factors such as the choice of splitter, splitting level, and splitting ratio. This guide delves into these pivotal aspects, offering a comprehensive understanding of FTTH network design.
