

Long-wavelength fiber optic communication systems

Overview

Modern fiber-optic communication systems generally include optical transmitters that convert electrical signals into optical signals, optical fiber cables to carry the signal, optical amplifiers, and optical receivers to convert the signal back into an electrical signal. Fiber-optic communication is a form of optical communication for transmitting information from one place to another by sending pulses of infrared or visible light through an optical fiber. The light is a form of carrier wave that is modulated to carry information. Additionally, optical fiber is. In this experiment, we applied a newly developed wavelength band conversion technology for the ultra-long wavelength band (U-band) 1 and demonstrated the world's first long-haul optical amplification relay transmission 2. Unlike traditional copper cables that rely on electrical signals, fiber optics use light pulses to carry data, offering unparalleled speed, bandwidth, and immunity to electromagnetic interference.
