

# Measurement of Low-Voltage Distribution Boxes

## Overview

Network topology is essential for the safe operation of a low-voltage (LV) distribution network. This network connectivity is difficult to obtain accurately due to the complex structure and low level of automation. In this paper, we first propose a four-level topology (which includes transformer, outlet cabinet, branch box, meter box) automatic identification method. Assuming that LVICBs are installed at each branch node of the network, and the electric quantity measurement data of these devices are collected at certain intervals through the TTU installed at the distribution transformer, the obtained data after a certain period form the measurement data matrix  $Z$ : This paper proposes a topology identification method for LV distribution network based on the CLS method and graph theory. The results obtained from the real distribution network scenario studies can be summarized as follows: We propose a method to automatically identify the four-level topological relationship (transformer, outlet cabinet, branch box, meter box).
