

Optical modules do not distinguish between transmit and receive

Overview

The optical transceiver, also simply known as an optical module or fiber optic transceiver, is an integration of a transmitter and receiver within a single module. An optical module is a typically hot-pluggable optical transceiver used in high-bandwidth data communications applications. As the core optoelectronic devices operating at the Physical Layer of the OSI model, their primary function is to perform electro-optical and photo-electric conversion during signal. As an essential component of optical fiber communication, optical modules are optoelectronic devices that facilitate the conversion between optical and electrical signals during the transmission process. Dual fiber modules use two fibers. They use a thin fiber. A transmitter converts an electrical data signal into an optical (or radio) signal and launches that energy into the physical medium.
