

The sensor's optical fiber passes near the motor

Overview

A fiber-optic sensor is a sensor that uses optical fiber either as the sensing element ("intrinsic sensors"), or as a means of relaying signals from a remote sensor to the electronics that process the signals ("extrinsic sensors"). Fibers have many uses in remote sensing. Depending on the application, fiber may be used because of its small size, or because no electrical power is needed at the sensing element. Intrinsic sensors Optical fibers can be used as sensors to measure temperature, strain, and other quantities by modifying a fiber so that the quantity to be measured modulates the light intensity, phase, or transit time. Extrinsic fiber-optic sensors use an external sensor, normally a photodiode, to transmit light from either a non-fiber optical sensor, or an electronic sensor connected to an optical transmitter. A major benefit of fiber-optic sensors is that they are immune to electromagnetic interference. It is well-known the propagation of light in optical fiber is confined in the core of the fiber based on the total internal reflection (TIR) principle and near-zero propagation loss within the cladding, which is very important for long-distance communication.
