

Two factors affecting optical receivers

Overview

Connector and splice losses are among the most common causes of signal attenuation in optical fiber systems. Every point where two fibers are joined—either via connectors or splicing—presents an opportunity for light to scatter or reflect due to misalignment, poor polishing, or. Receiver sensitivity refers to the minimum input optical power required by the receiver to achieve a specified bit error rate (BER). A larger receiver sensitivity indicates poorer receiver performance. To make a good optical receiver design, it is critical to understand the. In the world of high-speed fiber optic communication, optical receivers are vital for converting light signals back into electrical signals for further processing. A 3-dB increase in receiver sensitivity can be traded for a 3-dB reduction in optical transmit power, a 41% increase in free-space communication. An essential parameter in determining the system power budget in an optical transmission system is optical receiver sensitivity, defined as the minimum average optical power for a given bit-error rate (BER).
