

# What type of switch should be used in the primary distribution box

## Overview

Metal-clad switchgear is usually used for the primary ring bus. Although Primary Ring Bus System shows two utility sources, this system arrangement is easily expanded to incorporate additional utility sources. The symbology (low voltage circuit breaker, low-voltage drawout circuit breaker, medium voltage switch, medium voltage breaker) reflects the most commonly-used equipment for each arrangement. The radial system is the simplest system. As the main switch is separated from the whole distribution box, it can also be used as the power supply terminal (including bus bar) for the protection function of switching, and can also be used as the backup protection circuit of feeder. The power cabinet is a combination of electrical control. The simplest primary distribution system consists of independent feeders with each customer connected to a single feeder. Since there are no feeder interconnections, a fault will interrupt all downstream customers until it is repaired. It is a vital part and central hub of any electrical system. The hub distributes electrical power from a single input source to various circuits throughout a building. It receives a single, high-amperage power feed and divides it into multiple. Electrical distribution boxes are used in commercial and residential buildings and are part of the electrical system, also known as switchboards.
